ABSTRACT

With increase in demand for computers, iPods and mobile phones, there is surge of electronic gadgets around the world leading to production of huge quantity of waste termed as E-Waste. We have proposed an innovative solution for reduction of dumping and recovery of precious metals by harmful means from e-waste in developing countries. Manufacturing of laptops and computers using bioplastic which is partially biodegradable material and have life span of four to five years. By varying the composition of different bio-plastics, their thermal insulation, structural strength and conductivity can be improved. It would make them suitable material to replace acrylonitrile butadiene styrene based common plastic that are currently being used in manufacturing of different kind of laptops. The segregation of these bioplastic into its constituent’s materials would be much simpler and easier. This can be done by segregation of electronic components made from bioplastic at home or industry. Further, these bioplastic can be used as a feed for small community based pyrolitic units which will act as a source of syngas and bio-oil. The syngas produced can be used as fuel for cooking and also for supplying fuel to electricity generators. The biochar left in chamber when mixed with organic fertilizers can be act as source of manure to the soil. As a result with production of zero toxic constituents, these bioplastics can meet the ever increasing demands of laptops in developing countries like India.

Keywords: Biolap, bioplastic, generator, fertilizer, syngas

INTRODUCTION

Consumer electronics have increased production and have become culturally more important over the past several decades as it has changed how we communicate, or entertain, and get information.

| Table 1. Consumer electronics includes following items |
|---|---|---|---|
| Computer | Television | Hard Copy Devices | Mobile Devices |
| Laptops | CRTs | Printers | Cell phones |
| Desktops, Monitors | Flat –Panel Projection | Fax Machines Scanners | Smart Phones PDAs |
| Keyboards | Monochrome Copiers | Pagers |

Due to rapid technological advancement in this sector, there is constant stream of new and more enhanced products and as a result there is increase in generation of electronic waste.

E-waste consist of a many components, some containing toxic substances that can have an adverse impact on human health and the environment if not handled properly.

According to a report by UNEP titled, "Recycling - from E-Waste to Resources," the amount of e-waste being produced - including mobile phones and computers - could rise by as much as 500 percent over the next decade in some countries, such as India. The United States is the world leader in producing electronic waste, produces about 3 million tons each year. China is on second position producing about 2.3 million tons (2010 estimate) domestically. And, despite having banned e-waste imports, China remains a major e-waste dumping ground for major developed countries.

According to environmental Protection agency report in 2009:
- 438 million new electronic products were sold;
- 5 million short tons of electronic products were in storage;
- 2.37 million short tons of electronic products were ready for end-of-life management; and
- 25 percent of these tons were collected for recycling.

And in 2013 the numbers of computers being sold were 289,753,002 and number is constantly increasing. With such a large amount of electronic item being purchased all over the world it is creating a problem of how their disposal should be done in a most efficient way.
To curb this problem we have come up with an innovative solution of making of laptops of biodegradable material i.e. using of bioplastic in making of laptops which would be called BIO LAP.

Since acrylonitrile butadiene styrene which is common plastic used in making laptops is a petroleum based plastic. About 100 million tonnes of petroleum plastic is produced per year worldwide. About 7 million barrels of oil is used per day to make these plastics. Now imagine that number being significantly reduced if not dropping to zero. With the help of bio plastics, one day that may be a reality.

**BIOPLASTIC**

Bioplastics are similar to biomass plastics in that they are made by fermentation of plant sugars, which makes them carbon neutral and eliminates the need for non-renewable petroleum (oil) plastics. The difference is that bioplastics are, by definition, biodegradable or compostable, because their polymers are different from those derived from crude oil, and the chemical bonds are more susceptible to degradation by enzymes produced by natural microorganisms.

Examples of bioplastics are polylactic acid (PLA), polycaprolactone (PCL), polyhydroxybutyrate-covalerate (PHBV), and polyesteramide.

**Need for bioplastic**

Estimates suggest 200 billion pounds of plastic is produced every year. Due to the technical limitations or inconvenience of recycling, only a fraction of that material resurfaces in new plastic products.

The Pacific Ocean is home of the world's biggest landfill: the Great Pacific Garbage Patch and unlike biological material, plastic do not biodegrade and decompose. Instead, plastic photodegrades, i.e. it breaks down into infinitely into smaller and smaller pieces without actually chemically breaking down. As a result, the amount of plastic debris in the Great Pacific Garbage Patch only grows. The tiny plastic bits, called nurdles or "Mermaid tears," are reported to outnumber plankton in the vast region six-to-one and are mistaken as food by bottom feeders and other filter feeders, which poses a threat to the entire food chain.

Further research is taking place in making conducting material made up of bioplastic. Italian firm Bio-on's bioplastic -- which is totally biodegradable and made from sugarcane waste – can now become an electroconductor, by applying nanotubes containing graphene. These bioplastic can be used in making of printed wired board.

Bioplat even can be made more successful by using lead free soldering. In this type of soldering instead of lead, copper is used. Organic material which can be used to make bioplasd even more efficient

**Batteries** which are categorized harmful toxic waste can be made from rice husk as rice husk contains silica and this silica is converted to silicon and use it for high-capacity lithium battery anodes. Taking advantage of the interconnected nonporous structure naturally existing in rice husks, the converted silicon exhibits excellent electrochemical performance as a lithium battery anode, suggesting that rice husks can be a massive resource for use in high-capacity lithium battery negative electrodes. Research is already in progress at ‘Virginia tech laboratories’ to develop cheap biodegradable sugar batteries that can perform for about 3 years.

Organic led’s solution to the inorganic led using screens of laptops. The organic LED, OLED has many of the properties of a traditional organic LED. It is a PN junction cross which light flows Properties of OLED.

1. They are flexible and very thin which make them best suited for laptop.
2. They have very low power consumption.
3. They have wide viewing angle, high contrast ratio.
4. Faster time response.

Bioplastic made up of kenaef are even more successful as it has highest rates of CO₂ absorption of any plant. Its photosynthesis rate is 3 to 9 times higher than ordinary plants resins, and is capable of absorbing approximately 1.4 tonnes of CO₂ per ton of kenaf. It is thus a very effective plant in terms of global warming prevention. It is now being cultivated in Southeast Asia and many other countries around the world, mainly as a substitute for existing materials for uses such as paper fiber and livestock feed.

**Lifespan and end product of bioplastic**

Typical lifespan of laptop is about five year but they are often junked before they are broken because of new upcoming technologies, and the best part of bioplastic is that they also have working period of four years. Apart from the organic led and silica made batteries every component mentioned above have working period of four to five years.

Bioplastics require less energy to produce than conventional plastics, and they are made with renewable biomass. Since conventional plastics also accumulate in landfills and take thousands of years to biodegrade while many bioplastics can and should be composted, allowing them to biodegrade much more quickly. The result is less landfill usage, less pollution, and less waste accumulation in vulnerable ecosystems as well as a greatly reduced carbon footprint.

**Decomposition of BIOLAP- An Innovative solution**

Bioplastic can be used for making materials starting from cutlery to gadgets like mobile phones. For decomposition of
biolap innovative design is suggested. Using pyrolytic chamber to
de decompose the bioplastic instead of dumping for landfill because
methane is uncontrollably released during anaerobic
decomposition or using them as compost.

Since bioplastic contain about sixty percent of biodegradable
material it can be used as feed to the small pyrolytic chamber.
Electronic gadgets made from bioplastic are made to segregate at
home itself. And then these are used as feed in the pyrolytic
chamber. In this chamber biodegradable material would be heated
till the temperature of 350 degrees to 700 degrees Celsius. As a
result it would contain 35 and 50% biochar from the original
weight of the biomass; water; and a syngas.

The syngas produced can be further be used for:
1. Cooking food
2. Fuel for automobiles
3. Fuel for biodiesel generators which can act as back up units.
4. Nanocatalyst converts syngas into ethylene and propylene.

The key to this new process is ananocatalyst consisting of
iron particles only 0.00002 millimeters stabilized on a
carbon nanofibers and syngas is passed across the catalyst
and is converted to ethylene and propylene. Ethylene
molecules have two carbons linked together and propylene
molecules have three carbon chains. These molecules are
exactly the same as the molecules derived from petroleum.
In fact, they may have advantages in health and safety,
because they do not need to be purified of the many
carcinogenic and otherwise hazardous constituents of
petroleum.

Based on an analysis of two diagnostic samples of syngas from
a slow pyrolysis demonstration unit, the syngas stream had an
energy content of 8-10 mega joules/kilogram (MJ/kg) with mainly
consisting of 10-25% hydrogen (H2), 15-25% carbon monoxide
(CO), 8-15% methane (CH4), and smaller amounts of ethane,
propane, ethyl alcohol, and acetyl alcohol.

Further, after removal of inorganic material from biochar, the
material so left could be mixed with organic fertilizers and used as
manure for the crop.

To further increase the production of syngas and produce bio-
oil we can use heating elements i.e. connected across the gasifying
chamber. Using this setup even the end products are being used
without producing noxious gases or producing any hazardous
chemical compound.

COST ANALYSIS OF BIOPLASTIC

Bioplastics are moving out of the niche and into the mass
market. Although full market penetration is just beginning, a
bioplastic material as Bio-based plastic research and development
still make up for a share of investment in bioplastics and impacts on
material and product prices.

So initially product development like biolap would be costing
much but as seen that prices have continuously been decreasing
over the last decade. With rising demand, increasing volumes of
bioplastics on the market and rising oil-prices, the costs for
bioplastics will be comparable with those for conventional plastic
prices. According to the PRO BIP study conducted by the
University of Utrecht, bioplastics could technically substitute
about 85 percent of conventional plastics, so this is not a
realistic short- or mid-term development.

With a share of 1.2 million tonnes (2011) compared to 280
million tonnes total plastic production per year, bioplastics are
still only beginning to penetrate the market.10 However, with
increasing availability and a quickly expanding number of
products in diverse market segments, round 1.2 million tonnes.
But demand is rising with more and more sophisticated bioplastic
materials and products entering the market.

One of the biggest benefits for investment in bioplastic would
be for recycling waste workers who are made to recover precious
metals from PCB and laptops by burning them, which is resulting
in increased percentage of nickel, cadmium and their harmful
chemicals in their blood.

Also with increase in investment it can create jobs in rural areas
and in country like India where major part of GDP comes from
agricultural sector, bioplastic can bring huge boost to the sector.

FURTHER PROPOSED DEVELOPMENTS AND CONCLUSION

Since bioplastic are not fully biodegradable as they contain
considerable percentage of petroleum products in them, so further
development should be to make biobased plastic fully made of
organic materials having high strength and heat resistance. As
bioplastic could be a potential method to reduce e-waste.
